Wayne Zachary's PhD Thesis (1972)

- Studied 34 members of a karate club
- Found 78 links between members who regularly interacted outside the club
- The club splitted in two during the study
- 1=sensei, 34=president

Splitting into two communities:

Max-flow and Min-cut

Maximum flow: example 1

- If edge weights were capacities, what is the **maximum flow** that can be sent from s to t ?

Maximum flow: example 2

- If edge weights were capacities, what is the **maximum flow** that can be sent from s to t?

Maximum flow problem

- What is the maximum “flow” that can be carried from s to t ?
 - Think of edge weights as capacities (e.g. m^3/s of water)
- What is the flow of an edge?
 - The amount sent through that edge (an assignment)
- What is the net flow of a node?
 - The amount exiting the node minus the amount entering the node

Formulating the max flow problem

- The flow through each edge should be $\leq k_{ij}$
- Net flow at node h :
$$flow(h) = out_flow(h) - in_flow(h)$$
- Node s has only *out_flow*, should have positive flow v
- Node t has only *in_flow*, should have negative flow $-v$
- *What should be the flow of the other nodes?*

Formulating the max flow problem

- Let v be a feasible flow
- Node s should have positive flow v
- Node t should have negative flow $-v$

- *What should be the flow of an arbitrary node h ?*

$$\sum_{(h,j) \in \delta^+(h)} x_{hj} - \sum_{(i,h) \in \delta^-(h)} x_{ih} = ?$$

Max flow as a linear program

N: set of nodes. A: set of edges

$$\max \quad v \quad (1)$$

$$\sum_{(s,j) \in \delta^+(s)} x_{sj} = v \quad (2)$$

$$- \sum_{(i,t) \in \delta^-(t)} x_{it} = -v \quad (3)$$

$$\sum_{(h,j) \in \delta^+(h)} x_{hj} - \sum_{(i,h) \in \delta^-(h)} x_{ih} = 0, \quad h \in N - \{s, t\} \quad (4)$$

$$x_{ij} \leq k_{ij} \quad (i, j) \in A \quad (5)$$

$$x_{ij} \geq 0 \quad (i, j) \in A \quad (6)$$

Primal-Dual in Linear Programming

PRIMAL

$$\begin{aligned} \min \sum_j c_j x_j \quad & \text{subject to} \\ \sum_j a_{ij} x_j &\geq b_i \quad \forall i \in [m] \\ x_j &\geq 0 \quad \forall j \in [n] \end{aligned}$$

DUAL

$$\begin{aligned} \max \sum_i y_i b_i \quad & \text{subject to} \\ \sum_i y_i a_{ij} &\leq c_j \quad \forall j \in [n] \\ y_i &\geq 0 \quad \forall i \in [m] \end{aligned}$$

Writing the dual: each constraint will become a variable

$$\max \quad v \tag{1}$$

$$\sum_{(s,j) \in \delta^+(s)} x_{sj} = v \quad \text{variable } u_s \tag{2}$$

$$- \sum_{(i,t) \in \delta^-(t)} x_{it} = -v \quad \text{variable } u_t \tag{3}$$

$$\sum_{(h,j) \in \delta^+(h)} x_{hj} - \sum_{(i,h) \in \delta^-(h)} x_{ih} = 0, \quad h \in N - \{s, t\} \quad \text{variables } u_j \tag{4}$$

$$x_{ij} \leq k_{ij} \quad (i, j) \in A \quad \text{variables } y_{ij} \tag{5}$$

$$x_{ij} \geq 0 \quad (i, j) \in A \tag{6}$$

Writing the dual

- Remember: the infimum of the solutions of the dual is the supremum of the solutions of primal

$$\min \sum_{(i,j) \in A} k_{ij} y_{ij}$$

$$u_i - u_j + y_{ij} \geq 0, (i, j) \in A$$

$$-u_s + u_t = 1$$

$$y_{ij} \geq 0$$

(Think of y_{ij} as
0 or 1)

- Variables u_i don't enter the objective, only their difference is in the constraints
- We can set them arbitrarily, in particular $u_s = 0, u_t = 1$

Dual (after simplification)

$$\min \sum_{(i,j) \in A} k_{ij} y_{ij}$$

$$u_i - u_j + y_{ij} \geq 0, (i, j) \in A$$

$$y_{ij} \geq 0$$

$$u_s = 0, u_t = 1$$

- What happens with the values of u in every simple path going from s to t ?

Dual (after simplification)

$$\min \sum_{(i,j) \in A} k_{ij} y_{ij}$$

$$u_i - u_j + y_{ij} \geq 0, (i, j) \in A$$

$$y_{ij} \geq 0$$

$$u_s = 0, u_t = 1$$

Every feasible solution represents a cut (S, S')

Dual solutions are cuts

- Every feasible solution of the dual has the form of a cut (S, S')

Dual solutions are cuts

- Every feasible solution of the dual has the form of a cut (S, S')

Dual solutions are (s-t)-cuts

$u_i - u_j + y_{ij} \geq 0$ and remember we're trying to minimize $\sum k_{ij} y_{ij}$

One more thing about the solution

$$\min \sum_{(i,j) \in A} k_{ij} y_{ij}$$

$$u_i - u_j + y_{ij} \geq 0, (i, j) \in A$$

$$y_{ij} \geq 0$$

$$u_s = 1, u_t = 0$$

y_{ij} is a dual variable corresponding to primal constraint $x_{ij} \leq k_{ij}$

If y_{ij} is non-zero, then the corresponding constraint is tight

What does it mean for the edges in the cut?

This is an efficient method

- Min-cut and Max-flow are equivalent problems
 - Their solutions are also equal: the value of the maximum flow is equivalent to the minimum cut
- Think of a chain that breaks at the weakest link
- Both can be solved exactly in polynomial time

Randomized algorithm for (s-t)-cuts

Randomized algorithm for (s-t)-cuts

- Pick an edge at random (u, v)
- Merge u and v in new vertex uv
- Edges between u and v are removed
- Edges pointing to u or v are added as multi-edges to vertex uv
- When only s and t remain, the multi-edges are a cut, probably the minimum one

Example merges (“contractions”)

Try it!

Run the randomized algorithm on this graph

- Pick an edge at random (u, v)
- Merge u and v in new vertex uv
- Edges between u and v are removed
- Edges pointing to u or v are added as multi-edges to vertex uv
- When only s and t remain, the multi-edges are a cut, probably the minimum one

The randomized algorithm might miss the min cut

- Multiple runs are required
- The probability that this finds the min cut in one run is about $1/\log(n)$, so $O(\log n)$ iterations are required to find min cut
- Each iteration costs $O(n^2 \log n)$
- $O(n^2 \log^2 n)$ operations needed to find min cut
- Exact algorithm: $O(n^3 + n^2 \log n)$; the n^3 is because of $|V||E|$ operations required

Summary

Things remember

- Minimum s-t cut in a graph = set of edges
- The sum of the capacities of those edges is the maximum s-t flow the graph can carry
- Solvable in polynomial time
- Approximate randomized algorithm exists
