# Types of centrality measure

- Spectral
  - HITS
  - PageRank
- **Non-spectral**
  - Degree
  - Closeness and harmonic closeness
  - Betweenness

# Betweenness

# Node and Edge Betweenness

A node/edge has high betweenness if it participates in many shortest-paths

A: Degree

B: Closeness

C: Betweenness

D: PageRank

# Edge Betweenness

An **edge** has high betweenness if it is part of many shortest-paths ... how to compute this efficiently?

# Algorithm [Brandes, Newman]

- For every node  $u$  in  $V$ 
  - Layer the graph performing a BFS from  $u$
  - For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
    - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
  - For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by reverse layer
    - Score to distribute = 1 + score from children
    - Add score to parent edges in proportion to  $s(v)$
- In the end divide all edge scores by two

# Example

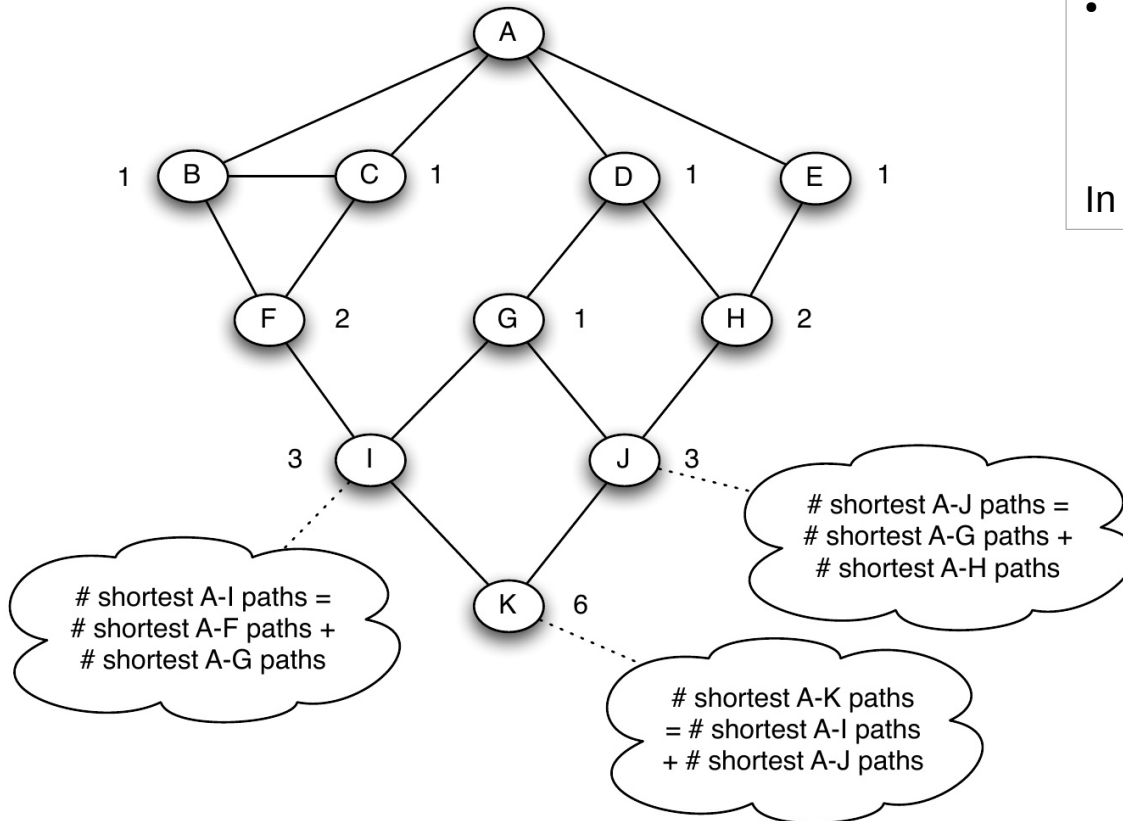

For every node  $u$  in  $V$

- Layer the graph performing a BFS from  $u$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
  - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by reverse layer
  - Score to distribute =  $1 + \text{score from children}$
  - Add score to distribute to parent edges in proportion to  $s(v)$

In the end divide all edge scores by two

# Example

For every node  $u$  in  $V$

- Layer the graph performing a BFS from  $u$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
  - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by reverse layer
  - Score to distribute =  $1 + \text{score from children}$
  - Add score to distribute to parent edges in proportion to  $s(v)$

In the end divide all edge scores by two

All nodes in layer 1 get  $s(v)=1$

Remaining nodes: simply add  $s(\cdot)$  of their parents

# Example

For every node  $u$  in  $V$

- Layer the graph performing a BFS from  $u$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
  - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
- **For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by rev. layer**
  - **Score to distribute = 1 + score from children**
  - **Add score to distribute to parent edges in proportion to  $s(v)$**

In the end divide all edge scores by two

Nodes without children distribute a score of 1

Other nodes distribute 1 + whatever they receive from their children

# Result

For every node  $u$  in  $V$

- Layer the graph performing a BFS from  $u$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
  - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by reverse layer
  - Score to distribute =  $1 + \text{score from children}$
  - Add score to distribute to parent edges in proportion to  $s(v)$

**In the end divide all edge scores by two**

Computed using NetworkX  
(edge betweenness)

# NetworkX code

```
import networkx as nx
g = nx.Graph()
g.add_edge("A", "B")
g.add_edge("A", "C")
g.add_edge("A", "D")
g.add_edge("A", "E")
g.add_edge("B", "C")
g.add_edge("B", "F")
g.add_edge("C", "F")
g.add_edge("D", "G")
g.add_edge("D", "H")
g.add_edge("E", "H")
g.add_edge("F", "I")
g.add_edge("G", "I")
g.add_edge("G", "J")
g.add_edge("H", "J")
g.add_edge("I", "K")
g.add_edge("J", "K")
nx.edge_betweenness(g, normalized=False)
```

`nx.draw_spring(g, with_labels=True)`

# Exercise

*Try to compute it by inspection first*

*Then use the algorithm;  
you should get the same results*

For every node  $u$  in  $V$

- Layer the graph performing a BFS from  $u$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by layer
  - Assign to  $v$  a number  $s(v)$  indicating how many shortest paths from  $u$  arrive to  $v$
- For every node  $v$  in  $V$ ,  $v \neq u$ , sorted by reverse layer
  - Score to distribute =  $1 + \text{score from children}$
  - Add score to distribute to parent edges in proportion to  $s(v)$

In the end divide all edge scores by two

Answer in Nearpod Draw-it  
<https://nearpod.com/student/>  
Access to be provided during class

# Fractional values?

- In a graph with cycles, you may get **fractional values** of the edge betweenness for an edge

# Application: the Girvan-Newman algorithm

- Repeat:
  - Compute edge betweenness
  - Remove edge with larger betweenness

# Summary

# Things to remember

- Closeness and harmonic closeness
- Node and edge betweenness
- Practice running the Brandes-Newman algorithm on small graphs
- Write code to execute the Brandes-Newman algorithm

# Practice on your own

- Compute edge betweenness on this graph

# Practice on your own (cont.)

If you don't get this result, check:

<https://www.youtube.com/watch?v=uYjWbp8VC7c>

# Two constructive problems

1. Sketch a graph of  $N$  nodes in which a node, which you should mark with an asterisk (\*), should have betweenness approximately equal to  $N$  and closeness approximately  $1/N$  for large  $N$ . Explain briefly.
2. Sketch a graph of  $N$  nodes in which a node, which you should mark with an asterisk (\*), should have betweenness approximately equal to  $N$  and closeness approximately  $2/N^2$  for large  $N$ . Explain briefly.

*Do not use a concrete  $N$ . Use a general  $N$ , for instance by using the ellipsis (...) to denote multiple nodes.*
